

I think a good mental model is giving users a panel - connected to the internet (maybe works locally to some extent) - where they can manage workspaces and everything possibly associated with it.

Somebody has to provide it, the internet work bodies won't.

And a single corporation can't design it. Even if multiple do, they will add bloat to it, they will club it with other products in the interface. Shouldn't that matter as a protocol designer?

REQ-PERSIST-001

A workspace SHALL survive the permanent loss or destruction of any individual client device.
A workspace SHALL NOT depend exclusively on any individual client device for its continued existence.

What ChatGPT called it makes sense to me:

Workspace Registry

Need of a machine independent registry -- MANAGEMENT

Users can also possibly not destroy a workspace easily, because websites are storing data specific to workspaces. Today on the internet, if I want to delete my account on a website, I have to do it with them. That should remain the same.

This creates the problem of management of workspaces.

We want a streamlined proposal for this.

Websites will charge for workspaces.

There are two concepts

- 1. Website Workspace
- 2. User Workspace

A user can spin up random workspaces, they can have the same website workspace on three different user workspaces. But the website workspace will need to be activated from the website services.

This means that their is no actual 1:1 association between Website Workspaces to User Workspaces.

Technically that means that workspaces can send the same key/identifier to a website. Two user workspaces can edit the same website workspace, parallel on two browser tabs on the same browser. This says something to websites designing multiple internet workspaces for users under same credentials.

We have (not exhaustive)

- 1. Concepts
 - Workspace
 - Workspace Identifier
 - Workspace Authority
- 2. Requirements
 - Persistence
 - Isolation
 - Concurrency
 - Recoverability
- 3. Protocol
 - Identity
 - Routing
 - Discovery
- 4. Management
 - Create
 - Archive
 - Recover
 - Rename
 - Enumerate
 - Authorize Devices
- 5. Application Integration
 - Workspace Mapping
 - Concurrent Access
 - Lifecycle
 - Billing

- Workspace Management
- Users can “name” the workspaces - associate different key-value pair user reference identifiers.
 - These names can be used on browsing interfaces to mark different workspaces
